

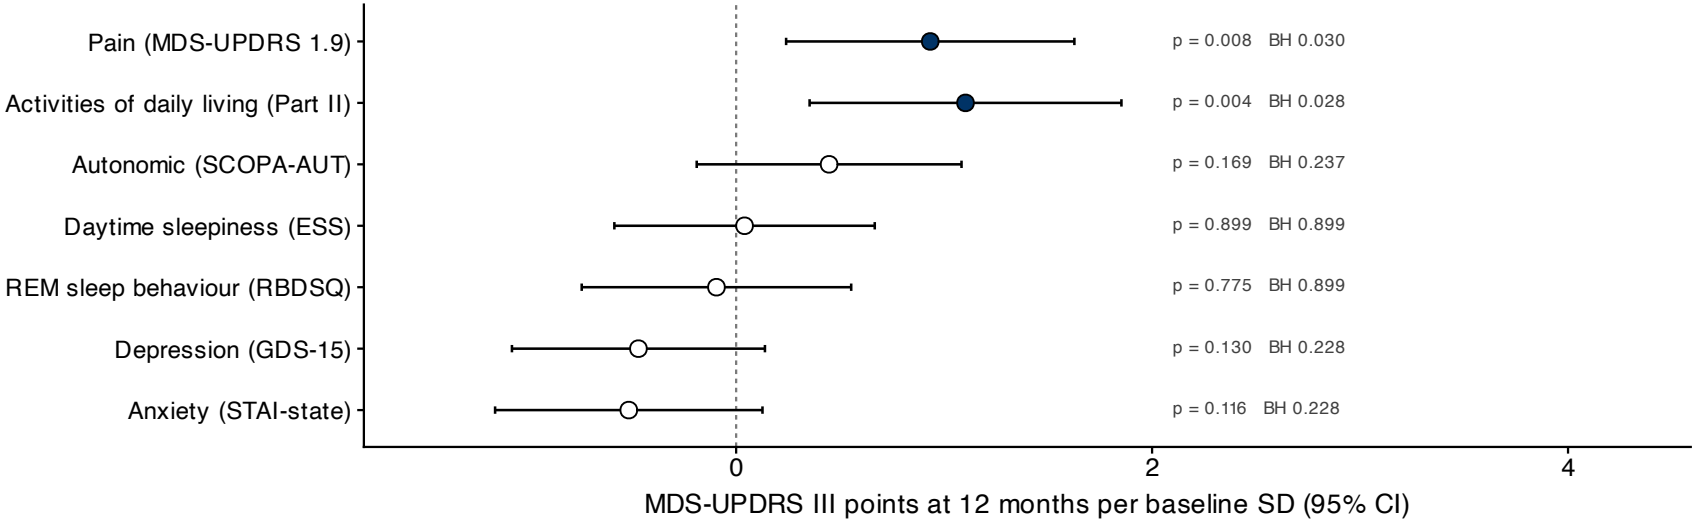

Figure 6. Which baseline symptoms predict motor severity at 12 months

All predictors are standardised and all models adjust for baseline motor score, age, sex, disease duration and MoCA, so the estimate refers to change. Pain and activities of daily living are the only two associated with the 12-month motor score. Pain survives Benjamini-Hochberg correction ($p = 0.030$) but not Holm ($p = 0.051$), and this should temper the claim. BH, Benjamini-Hochberg adjusted p value.
